ABSTRACT

Introduction: Rheumatoid arthritis (RA) is a chronic progressive autoimmune disorder characterized by symmetric erosive synovitis. The pathogenesis of bone erosion and joint deformities is not fully understood. The aim of this study was to find out vitamin C and E levels along with the lipid profile in newly diagnosed cases of RA. Materials and Methods: The patients for the study were selected from individuals attending the routine checkup in an Outpatient Department. Based on the criteria led by the American Rheumatism Association (ARA), the newly diagnosed patients were taken as cases and other normal individuals were taken as control group in the study. A total of 50 subjects were included in the study with the age group of 48 ± six years for both genders. Serum Vitamin-E was determined by the colorimetric method and serum Vitamin-C was estimated by the dinitro phenyl hydrazine method. Serum total cholesterol, HDL-cholesterol, triglycerides, and VLDL levels were estimated by the enzymatic method. LDL-cholesterol was calculated by the Friedewald's formula. Results: The levels of nutritional antioxidants vitamin E and C were different significantly in RA patients compared to control group. The lipid profile parameters were also different significantly in RA patients compared to the controls. Conclusion: Patients with RA presented with an imbalance in the oxidant-antioxidant system that markedly increased lipid peroxidation products and significantly decreased lipid soluble antioxidant vitamin E. These changes might play a role in the tissue damage and inflammation process in this disease.

KEY WORDS: Nutritional antioxidants, Rheumatoid arthritis, Lipid profile

INTRODUCTION

Rheumatoid arthritis (RA) is a chronic progressive autoimmune disorder characterized by symmetric erosive synovitis. Exact reasons behind bone erosion and joint deformities are not fully understood. Formation of reactive oxygen species and lipid peroxides as a result of disease activity may play an important role in RA. The antioxidants which prevent damage by free radicals have been shown to be decreased and one of the reasons for occurrence of RA.2

RA is characterized by persistent inflammation in the synovial membranes of joints, associated with migration of activated phagocytes and other leukocytes into synovial and periarticular tissue.3 During phagocytosis, monocytes, neutrophils and macrophages generate superoxide radicals, hydrogen peroxide and the highly reactive hydroxyl radicals.4 These cytotoxic reactive oxygen species (ROS) may cause oxidative damage in the cells.5 Activated oxygen intermediates together with highly reactive radicals, such as the hydroxyl radicals, are able to destroy membrane lipids, proteins, deoxyribonucleic acid, hyaluronic acid, and cartilages.6 Enzymatic mechanisms include superoxide dismutase (SOD), catalase and glutathione peroxidase (GPX). Vitamins A, C, E and glutathione are some of the major non-enzymatic antioxidants in the body.7,8 Studies have shown that concentrations of vitamin C, vitamin E and beta-carotene were found to be decreased in patients with RA.9,10

This study was conducted to determine the vitamin C, E levels and the lipid profile in newly diagnosed cases of RA patients.

MATERIALS AND METHODS

The patients for the study were selected from individuals attending the routine checkup in the Outpatient Department, and the study duration was one year. Diagnosis of RA patients was done based on clinical history such as morning stiffness in and around
joints, serological investigation like serum rheumatoid factor and radiographic changes such as erosions or unequivocal bony decalcification on hands and wrists. Based on criteria led by American Rheumatism Association (ARA), the newly diagnosed patients were taken as cases in the study and other individuals were taken as controls. After obtaining the institutional ethical committee clearance, with the informed consent for both cases and controls, the fasting blood samples were taken.

A total of 50 subjects were included in the study with the age group of 48 ± 6 years for both genders. Exclusion criteria were those having clinical history of the diseases such as diabetes mellitus, cardiovascular diseases, inflammatory diseases, infectious diseases, and already diagnosed cases of RA. Control subjects as well as RA patients were not on vitamin, minerals, any drug or such supplementation, which may alter antioxidant levels.

Blood samples obtained from the subjects were centrifuged at 3000 rpm for 5 minutes and the plasma wasSerum total cholesterol, HDL-cholesterol, triglycerides, and VLDL levels were estimated by the enzymatic method. LDL-cholesterol was calculated by the Friedewald's formula. Statistical Analysis

Statistical analysis was done using students t-test and the values expressed as mean ± SD. Correlation between the variables was estimated by Pearson’s correlation coefficients. SPSS 13.0 version was used for the analysis.

RESULTS

The results of the study were shown in Table 1. The levels of nutritional antioxidants were decreased significantly (Vitamin E- p<0.001 and Vitamin C- p<0.05) in RA patients when compared to control group. Furthermore, the lipid profile parameters such as the cholesterol and LDL levels were statistically significant (p<0.001) in cases when compared to controls. Total cholesterol, triglycerides, LDL cholesterol and VLDL cholesterol were significantly elevated whereas HDL cholesterol was significantly reduced.

DISCUSSION

Should rheumatologists be caring their patient’s cardiovascular and lipid status? The answer to this question is ‘yes’. Several studies suggested that cardiovascular diseases accounted for about half of all deaths in RA. Cardiovascular deaths are more pronounced in the younger age group (<55 years), and may contribute to the substantial reduction in life expectancy, with estimates of standardized mortality ratios ranging from 1.1 to 3.16

This increased cardiovascular risk in RA patients could be from several causes. Firstly, the prevalence of new or established cardiovascular risk factors, such as dyslipidemia, diabetes mellitus, hypertension, higher body mass index (BMI), higher waist to hip-ratio or impaired physical fitness, might be increased.17,18 Secondly, under treatment of risk factors may play a role.19 Finally, RA itself, particularly its chronic inflammatory component, could be an independent cardiovascular risk factor.20

In our study, we found a deranged lipid profile in RA patients which favours atherogenesis even in the newly diagnosed RA patients.

Previous studies suggested that cardiovascular disease in RA may result from accelerated atherosclerosis caused by clinical or subclinical vasculitis. The main determinants of cardiovascular risk in the general population, however, are the concentrations of serum low-density lipoprotein (LDL) and high-density lipoprotein (HDL) cholesterol. In men who are middle-aged or over, a ratio of total to HDL cholesterol over 5 is associated with increased risk of a first myocardial infarction.3 Oxidative modification of LDL may also be important, and it is of interest that
oxidised LDL has been noted in RA synovial biopsy specimens. These oxidised products have to be neutralized by antioxidants present in the body, which was evident in our study, as vitamin E and C levels were decreased in RA patients. This was in agreement with a study done by Heliovaara et al.21 which demonstrated that a low antioxidant level was a risk factor for development of RA disease. It is possible that vitamin E was consumed in the process of counter-balancing the free radicals. A decrease in plasma vitamin E was also observed in juvenile rheumatoid arthritis.9

Vitamin C is one of the most efficient water soluble antioxidants. Our findings revealed that the levels of vitamin C in RA patients decreased significantly when compared to controls and was in accordance with Situnayake et al.22 who reported a significant decrease in plasma vitamin C levels in RA patients with moderately active inflammatory activity, and 70% of these patients were seropositive for rheumatoid factor.

The inflammatory environment and disturbed antioxidant mechanisms in RA8 may promote LDL oxidation, thereby facilitating atherogenesis at lower ambient lipid concentrations and placing RA patients at higher cardiovascular risk.

CONCLUSION

We conclude that patients with RA present with an imbalance in the oxidant-antioxidant system that markedly increased lipid peroxidation products and significantly decreased lipid soluble antioxidant vitamin E. These changes might play a role in the tissue damage and inflammation process in this disease.
